

#1.

- a) Totalamount, _usercount, \$price, signal_3
- b) class (can't be reversed key), total# (illegal character), 3age(can not start with a number), first name(can not contain space)

#2. `int numBeads;`

`numBeads = 5;`

`Int numBeads = 5;`

#3.

- a) 4
- b) 11

#4

- A) Int
- B) Double
- C) Int
- D) Double
- E) Int
- F) int

#5

- a) Primitive data is premade in the programming language, abstract is a conceptual model
- b) Class is basically the blueprint of the code while object is the actual physic object of the code

#11

`y = (int) Math.round(j * k);` , explanation : multiplying an int by a double will result in a double output. You must use `Math.round()` to prevent truncation and cast it with `(int)` to fit inside the integer variable `y`.

`z = j * k;` The type match perfectly without needing type casting
